Knowledge Organiser: Pandas

Pandas is a software library written for the Python programming language for data manipulation and analysis. In particular, it offers data structures and operations for manipulating numerical tables and time series.

Creating DataFrames

		a	b	c			
	1	4	7	10			
	2	5	8	11			
	3	6	9	12			
<pre>df = pd.DataFrame(</pre>							

```
df = pd.DataFrame(
    [[4, 7, 10],
    [5, 8, 11],
    [6, 9, 12]],
    index=[1, 2, 3],
    columns=['a', 'b', 'c'])
Specify values for each row.
```

			a	b	c
D e	N	٧			
		1	4	7	10
		2	5	8	11
	e	2	6	9	12

Summarize Data

df['w'].value counts()

Count number of rows with each unique value of variable len(df)

of rows in DataFrame.

df.shape

Tuple of # of rows, # of columns in DataFrame.

df['w'].nunique()

of distinct values in a column.

df.describe()

Basic descriptive and statistics for each column (or GroupBy).

pandas provides a large set of <u>summary functions</u> that operate on different kinds of pandas objects (DataFrame columns, Series, GroupBy, Expanding and Rolling (see below)) and produce single values for each of the groups. When applied to a DataFrame, the result is returned as a pandas Series for each column. Examples:

sum()

Sum values of each object.

count()

Count non-NA/null values of each object.

median()

Median value of each object.

quantile([0.25,0.75])
Quantiles of each object.

apply(function)

Apply function to each object.

min()

Minimum value in each object.

max()

Maximum value in each object.

Mean value of each object.

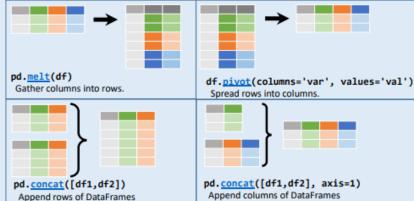

var()

Variance of each object.

std()

Standard deviation of each object.

Reshaping Data – Change layout, sorting, reindexing, renaming

df.sort values('mpg')

Order rows by values of a column (low to high).

df.<u>sort_values('mpg', ascending=False)</u>
Order rows by values of a column (high to low).

df.rename(columns = {'y':'year'})
Rename the columns of a DataFrame

df.sort index()

Sort the index of a DataFrame

df.reset_index()

Reset index of DataFrame to row numbers, moving index to columns.

df.drop(columns=['Length', 'Height'])
Drop columns from DataFrame

Subset Observations - rows

df[df.Length > 7]

Extract rows that meet logical criteria.

df.drop_duplicates()

Remove duplicate rows (only considers columns

df.sample(frac=0.5)

Randomly select fraction of rows.

df.sample(n=10) Randomly select n rows.

df.nlargest(n, 'value')
Select and order top n entries.

df.nsmallest(n, 'value')
Select and order bottom n entries.

df.head(n)

Select first n rows.

df.tail(n)

Select last n rows

Handling Missing Data

df.dropna()

Drop rows with any column having NA/null data.

df.<u>fillna</u>(value)

Replace all NA/null data with value.

Subsets - rows and columns

Use df.loc[] and df.iloc[] to select only rows, only columns or both.

Use df.at[] and df.iat[] to access a single value by row and column.

First index selects rows, second index columns.

df.<u>iloc</u>[10:20]

Select rows 10-20.

df.<u>iloc</u>[:, [1, 2, 5]]

Select columns in positions 1, 2 and 5 (first column is 0).

df.<u>loc</u>[:, 'x2':'x4']

Select all columns between x2 and x4 (inclusive).

df.loc[df['a'] > 10, ['a', 'c']]
 Select rows meeting logical condition, and only

Select rows meeting logical condition, and only the specific columns .

df.<u>iat</u>[1, 2] Access single value by index

df.at[4, 'A'] Access single value by label

Plotting

df.plot.hist()
Histogram for each column

df.<u>plot</u>.scatter(x='w',y='h')

Scatter chart using pairs of points
